INDIAN INSTITUTE OF TECHNOLOGY, KHARAGPUR

Instructions: Answer All The Questions.

Translate the following C function to GCC-x86 assembly language code. Write brief comments in each line explaining the translation. [10]

int bad(int n){
 int i, sum=0;
 for(i=0; i<=n; ++i) sum += i;
 return sum;
}</pre>

Assume that addresses of n, i and sum are (ebp) + 8, (ebp) - 4, and (ebp) - 8 respectively. Following are a few x86 assembly language instructions: add1 cmpl jle jmp leave movl push1 ret sub1

- 2. The object language alphabet Σ is the set of all ASCII characters except the following 13 characters: $\{\cdot\}$ [] () + *?\|"}. They have special meaning in the expressions. These characters are included in Σ using \e.g \[is treated as '['. [5+5+5]]
 - (a) Give a context-free grammar(CFG) for the set of regular expressions defined as follows:
 - i. ε , \emptyset , $a \in \Sigma$, n, t are regular expressions.
 - ii. (dot), "x", [x], where $x \in \Sigma^+$ are regular expressions.
 - iii. If r and s are regular expressions, then so are (r), (r|s), (rs), r*, r+, r?, $r\{m,n\}$ are regular expressions, where $0 \le m \le n$
 - (b) Give a regular expression for the floating-point numbers written either in e (2.5e+1) or in f (25.0) format. Sign of the number is not part of it.
 - (c) Give a DFA, corresponding to the regular expression of part (b) (no formal construction is required).
- 3. Consider the following ambiguous grammar with the usual meaning of the operators:

 $E \rightarrow B \mid A$

 $B \rightarrow B \text{ or } B \mid B \text{ and } B \mid \text{not } B \mid (B) \mid true \mid false \mid R$

 $R \rightarrow A < A \mid A = A \mid A <= A$

 $A \rightarrow A + A | A - A | A * A | A / A | (A) | -A | * A | ic | id$

The non-terminals are $\{E, B, R, A\}$ with E as the start symbol. [5 + 5 + 10]

(a) Write an equivalent unambiguous grammar for the language so that the natural precedence and associativity rules are embedded in the grammar. Orders of precedence are:

or < and < not; $\{+-\} < \{*/\} < \{-*\}$ (unary).

- (b) Remove left-recursions from the unambiguous grammar you have got in (a), and left-factor the production rules if necessary. Is the transformed grammar LL(1)?
- (c) Write pseudo code for a recursive-descent predictive parser for the Boolean expression part of the grammar starting from the non-terminal B. Assume A to be a terminal.
